Covid-19 and malaria global distribution

Covid-19 distribution

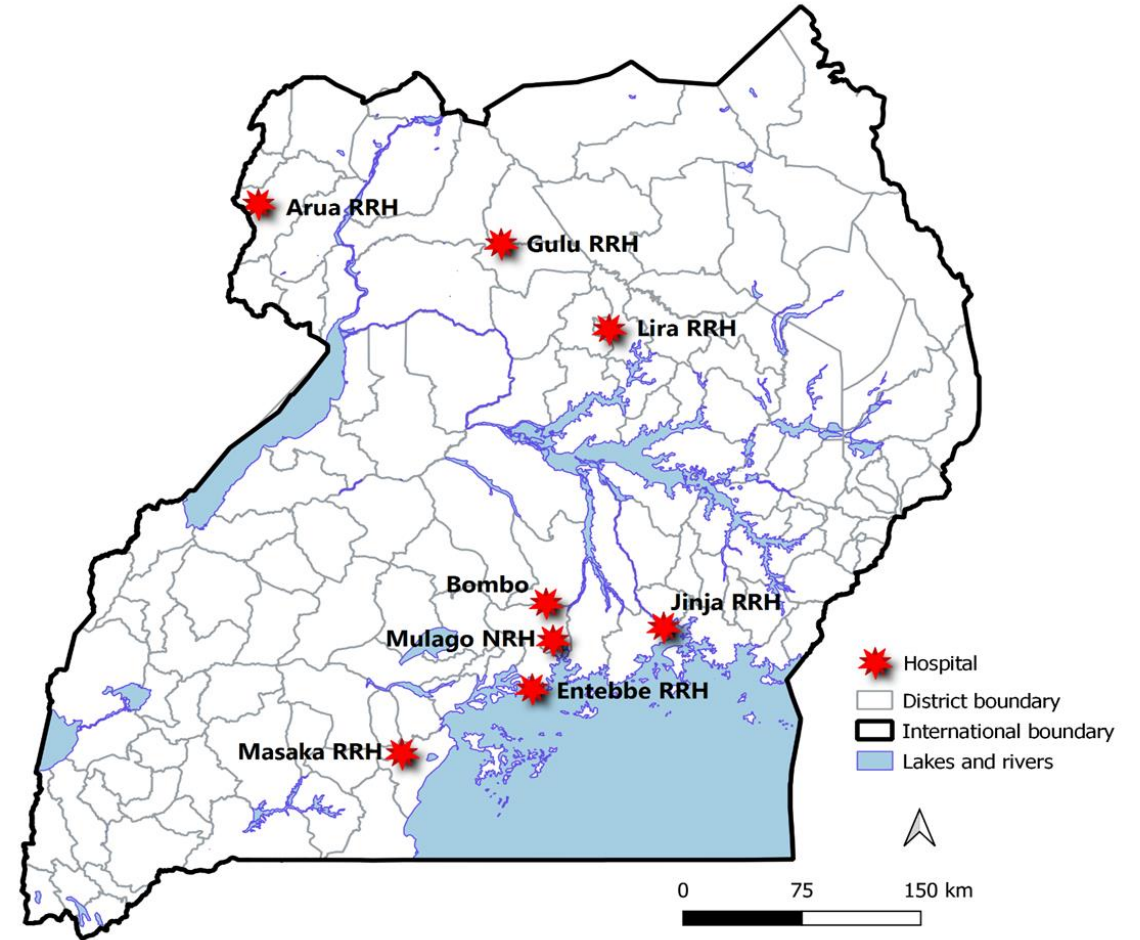

Malaria distribution

Background

- Despite the global spread of the SARS-CoV-2 virus, understanding of the epidemiology and clinical course of COVID-19 in sub-Saharan Africa is limited.
- The impact of COVID-19 on control of other infectious diseases and potential implications of any clinical interactions with these diseases remains a major public health concern.
- This study was conducted to
 - better characterise COVID-19 in a high malaria transmission setting
 - Determine the burden/describe the clinical impact of SARS-CoV-2 and malaria co-infection.

Methods

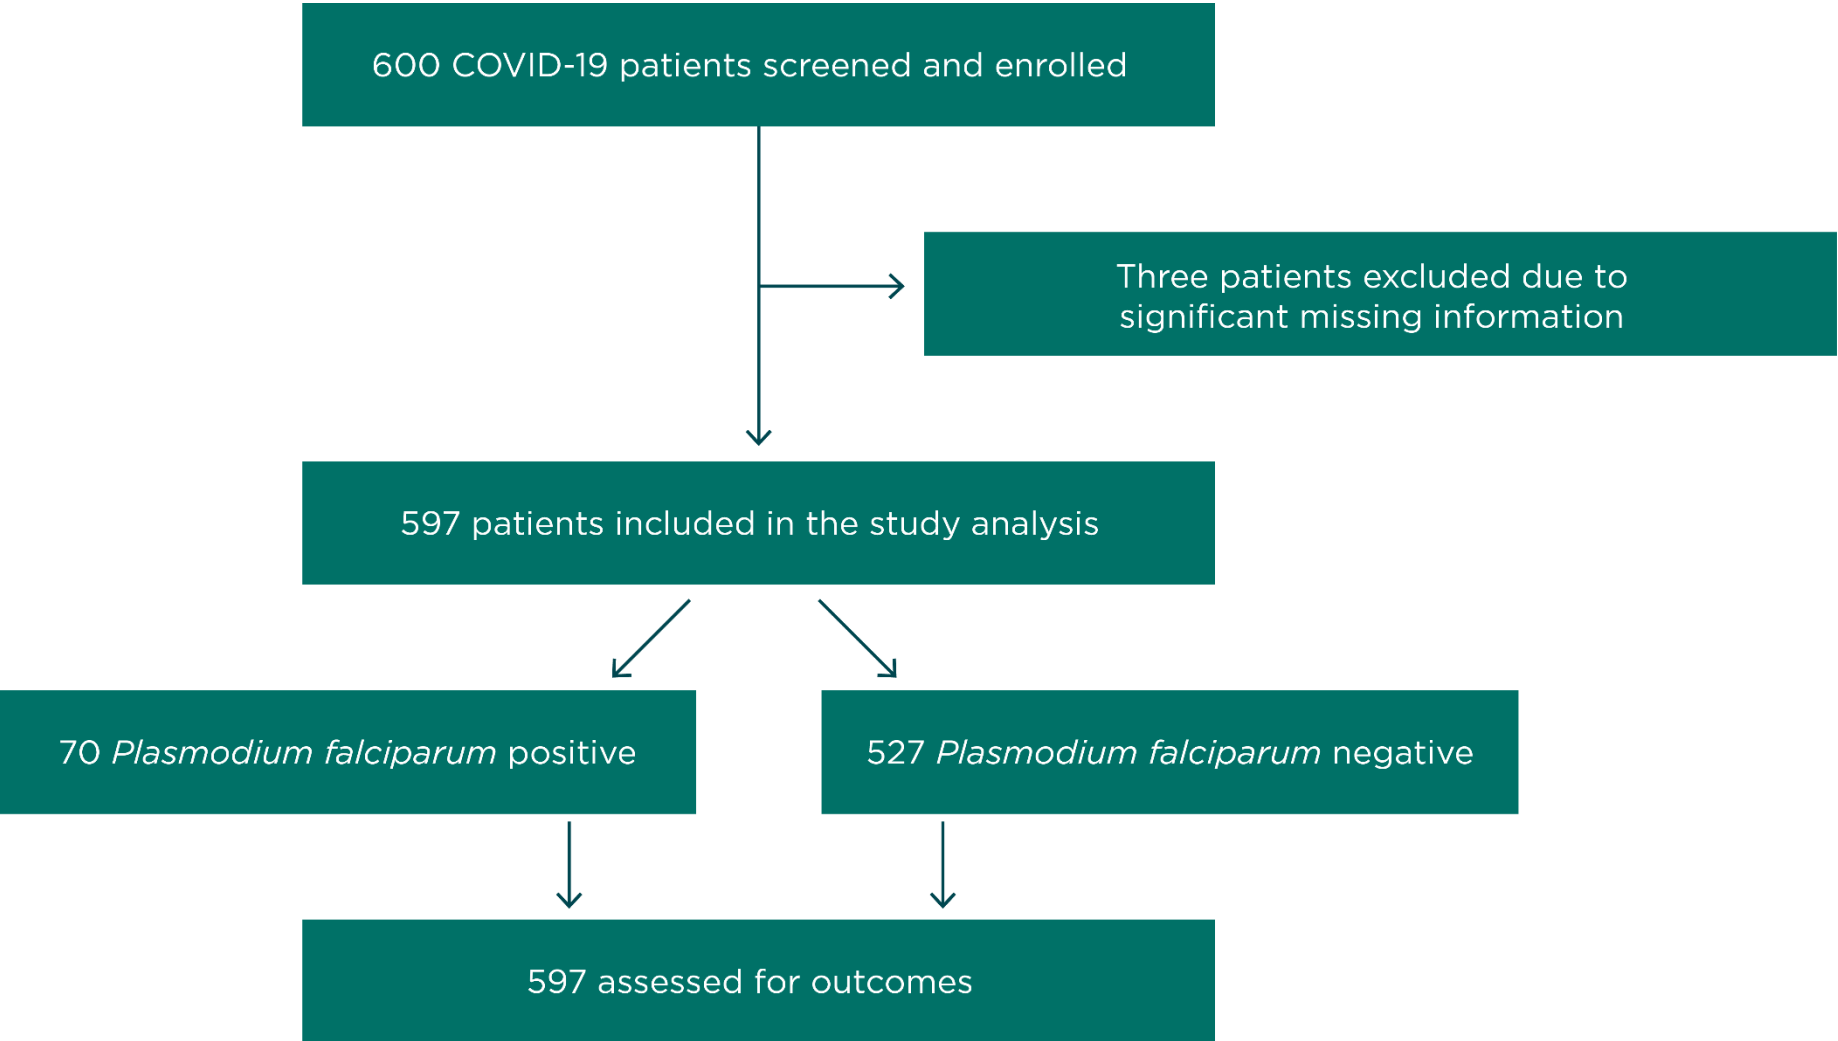

- **Study design:** Exploratory cohort study
- **Study sites:** Treatment centres in eight tertiary hospitals in Uganda
- **Sample size:** 600 polymerase chain reaction (PCR) confirmed COVID-19 patients
- **Timelines:** 15th April – 30th October 2020

Methods

- Malaria diagnosis: rapid diagnostic tests, microcopy and molecular analysis (qPCR)
- Previous individual *Plasmodium falciparum* exposure measured using serologic responses to a panel of antigens associated with cumulative/recent exposure
 - apical membrane antigen-1 (AMA-1), merozoite surface protein1.19 (MSP1.19) and glutamate-rich protein (GLURP.R2)
 - reticulocyte-binding protein homologue (Rh2.2030), gametocyte exported protein (GEXP18) and Early transcribed membrane protein (Etramp5.Ag1)
- Clinical Labs: Complete blood count, liver and renal function tests, HIV test
- Markers of inflammation: C-Reactive protein (CRP), Interleukin (IL)-2, IL-6, IL-7, IL-8, IL-10, transforming growth factor beta (TGF- β), tumor necrosis factor (TNF- α)
- Laboratory personnel unaware of patients' clinical status to avoid potential bias
- Clinical management conducted according to Ministry of Health guidelines.

Study Profile

Cytokines, Covid-19 severity, malaria infection status and previous malaria exposure

- No differences in cytokine levels among patients with or without malaria except for TNF- α which was higher in malaria positive patients.
- IL-6, IL-7, TNF- α and TGF- β 1 levels were higher among patients with more severe Covid-19 presentation.
- IL-6 and IL-10 were higher among patients with unfavorable outcomes.
- No significant elevation in IL-2 was observed in this patient population.

Conclusions

- Prevalence of *P. falciparum* infection among hospitalised COVID-19 patients in this population was 12 percent.
- Though COVID-19 patients with *P. falciparum* infection had a higher frequency of confusion and vomiting, co-infection with malaria did not seem deleterious.
- The association of low previous malaria exposure with severe/critical COVID-19 and adverse outcomes requires further study.
- These preliminary observations highlight the importance of understanding the potential clinical and therapeutic implications of such overlapping co-infections in similar settings.
